Preliminary demo runbook and acceptance record

Group 11 · PR2 November 12, 2026 · Prepared by Emily · Team rehearsal pending.

Proposed run of show (confirm with the team)

Presenter	Segment	Evidence and handoff
Gordon	Scope, consumer GUI and service discovery	Show real registry lookup/navigation only if connected; label existing simulated data.
Max	S2 API and stock-return calculation	Use its documented endpoint and tests; current branch audit passed 39 tests.
Emily	Module/C&C/communication views; S4/S5 validation and calculation	Explain source boundaries, demonstrate invalid inputs and show offline numerical tests.
Aashka	Registry, leases, deployment and S3	Demonstrate actual registry behavior; disclose open S3 review issues and cloud state.

This is a proposal, not confirmation that team members rehearsed or accepted their segments. Measure presentation time once the instructor's allotted duration is confirmed. Keep a local PDF/slide copy and test outputs as a fallback.

Safe local sequence

1. Record the exact commits for the demonstrated branches. Use separate worktrees or processes from independent checkouts; do not switch files under a running server. 2. Install each branch's requirements in a virtual environment. Run the offline suites first. Current new-code results: S4 56, S5 61 tests passing. 3. Start S4 on port 5004 with python s4_server.py and S5 on port 5005 with python s5_server.py. Without REGISTRY_URLS, each API runs independently. 4. Show /health (200), /service-info (metadata), a missing-input request (400), and an invalid date or duplicate S5 symbol request (400). These need no key. 5. Explain successful numerical calculations using the fixed test datasets. Do not describe mocked prices as real market observations. 6. To show real provider results, configure an entitled ALPHA_VANTAGE_API_KEY in the server terminal and restart. Full history needs premium access; no actual key is configured yet. User-selected symbols and dates are the request inputs. 7. To show leases, start the team's registry image in Docker (Docker must be running), set REGISTRY_URLS and SERVICE_PUBLIC_URL for each service, then restart both service runners. Inspect GET /services for S4 and S5. 8. Stop S4 with Control+C. Wait for lease expiry (roughly 12 seconds after its last renewal). Confirm S4 disappears and S5 still returns health 200. Explain that the current registry has no immediate deregistration API. 9. Show browser discovery/invocation only after GUI integration has been verified. A label-only failover toggle is not an actual automatic failover demonstration.

Example local registry setup, using the team's image:

docker run --rm --name pr2-registry -p 5000:5000 aashkaaa/stock-registry:latest

In each service terminal, before starting the runner:

export REGISTRY_URLS='http://localhost:5000'

Use 5005 for S5; deployed URLs must be reachable by consumers.

export SERVICE_PUBLIC_URL='http://localhost:5004'

Acceptance matrix

Check	Expected	Current evidence / status
S4 invalid dates/missing input	JSON 400 before provider calls	Automated tests passed.
S5 duplicate/bad symbols	JSON 400 without partial ranking	Automated tests passed.
S4 20/50-session means	Match fixed reference, round only final output	Automated tests passed.
S5 ranking/ties/common dates	Unrounded ranking, deterministic ties, correct shared endpoints	Automated tests passed.
Provider failures	Explicit rate-limit/timeout/error; later valid request succeeds	Mocked recovery tests passed. Live failure injection pending.
Registry source integration	Both services visible, S4 removal leaves S5 healthy	Local real HTTP test passed; 11.41-second removal observed.
Provider live access	Valid authenticated response for selected symbol	Pending: user has no key configured.
One-year completeness	Every expected session validated for the selected run	Pending: entitled key and actual run.
Discovery descriptions	Name, description, URL present	Registry currently drops descriptions; owner fix pending.
Immediate shutdown deregistration	Explicit agreed deletion if required	Not supported by current image; lease expiry is implemented.
Consumer GUI end to end	Discovery to service to actual displayed result	Pending team integration.
Cloud independent deployment	Published URLs and isolation under removal	Pending cloud-owner evidence. Local evidence does not establish this.
Three quality views	Templates and behavior models for all three	Emily communication packet prepared; other two await Gordon/team.
Human rehearsal / final acceptance	Timed run and recorded outcomes	Not performed by document generation.

Known remaining actions and fallback

For a key/quota failure, show the honest structured error and the offline tests. For unavailable Docker/cloud, show the recorded local registry evidence and state the environment it used. Use the diagrams to explain intended integrations, with dashed links labelled planned. Do not mark a deployment or live-data task complete from a screenshot of an isolated health endpoint.

Before submission, merge the team's other quality views and latest GUI/cloud evidence, confirm each presenter, rehearse, update the workbook statuses, and verify the actual OWL cutoff. No OWL submission or human rehearsal is automated here.
