AI assistance comparison and lessons learned — review draft

Prepared for task 6.22. This records the assistance actually used; it does not invent an independently authored student solution or claim a rehearsal occurred. The team must review its course AI rules and finalize its own reflection.

Work item	Student/team starting point	AI-assisted result	Comparison / limitation
S4/S5 algorithms	User supplied service definitions and requirements; no independently written baseline implementation supplied.	Calculation modules, API/source adapters, validation and tests prepared in requested branches.	Compare against specified formulas and fixed independent references, not invented manual work.
Provider access	Team selected Alpha Vantage; user has no key configured.	Request-driven retrieval, explicit compact/full coverage and credential-safe failures.	Code/test completion is different from successful authenticated retrieval. No one-year live dataset claimed.
Registry lifecycle	Team image and S3 client existed; delete contract was undocumented.	Image source inspected read-only; lease client registers/renews both registries and stops on shutdown.	Real local test verifies removal/isolation; immediate deletion and description retention remain upstream work.
Architecture packets	Team workbook and project brief specified views; current branches were separate.	Module, C&C and communication packets with diagrams, catalogue, context, variability, rationale and limitations.	Team review is needed to confirm its design intent; implemented/planned links are deliberately distinguished.
Planning	Workbook contained duplicated-looking data blocks and conflicting summary statuses.	Per-service scope labels, evidence notes, rollups, dependencies and complete chart rules in a copy.	Existing owners retained; unverified live/cloud/rehearsal work is not marked complete.
PR review	S3 branch included failure paths and simulated fallback values.	Reproduced failures and submitted changes-requested review.	Passing a normal request is not sufficient evidence for safe failure behavior.

Lessons supported by this work

1. Test errors and insufficient observations, not only normal data. Independent fixtures expose denominator, missing-session and rounding mistakes. 2. Inspect the actual integration contract. An assumed deregistration endpoint would have been wrong for the published registry image. 3. Separate different evidence levels: source inspection, unit tests, real local HTTP tests, authenticated provider access and cloud GUI acceptance. 4. Keep credentials out of commits, exception strings and generated artifacts. 5.

AI-generated diagrams must be checked against source branches; planned edges and missing components should remain visible rather than implied complete.

Team completion fields

Add each member's own comparison against any independently authored solution, their actual edits, and their own lessons. Confirm reference/AI disclosure rules with the course instructions. This draft does not substitute for that reflection.
